

601.220 Intermediate Programming

Spring 2023, Day 12 (February 17th)

Today's agenda

- Exercise 11 review
- Pointer arithmetic, “dynamic” 2-D arrays
- Exercise 12

Reminders/Announcements

- HW2 due **this evening** by 11 pm
 - Written assignment, late submissions not accepted
- HW3 due Friday, Feb 24th 8pm
 - challenging
 - recursion

Exercise 11 review

`pairwise_sum.c`: When running the program using `valgrind`:

```
valgrind --leak-check=full ./pairwise_sum
```

A memory leak is reported:

```
==17736== 16 bytes in 1 blocks are definitely lost in loss record 1 of 1
==17736==    at 0x483B7F3: malloc (in /usr/lib/x86_64-linux-gnu/valgrind/vgpreload_memcheck-amd64-linux.so)
==17736==    by 0x10922B: pairwise_sum (pairwise_sum.c:28)
==17736==    by 0x109399: main (pairwise_sum.c:57)
```

`valgrind` indicates there is a memory leak: the memory is allocated in `pairwise_sum.c` at line 28

Exercise 11 review

In the code:

```
int *pairsum2 = pairwise_sum(pairwise_sum(array, 5), 4);  
// ...  
free(pairsum2);
```

Issue: `pairwise_sum` returns a pointer to a dynamically allocated array, but for the “inner” call, the array is never freed.

Fix:

```
int *a = pairwise_sum(array, 5);  
int *pairsum2 = pairwise_sum(a, 4);  
// ...  
free(pairsum2);  
free(a);
```

Exercise 11 review

`primes.c`:

Issue: the `set_primes` function needs to call `realloc` if the array of results needs to be increased in size.

However, `realloc` can and usually does return a pointer to a new dynamic array (with a different memory address).

Unless `set_primes` can modify the list pointer in `main`, the `main` function has no way of knowing the address of the re-allocated array.

Exercise 11 review

Sketch showing the problem with the original code:

Exercise 11 review

Solution: change `set_primes` so that it takes a pointer to the list pointer variable in the main function.

// set_primes function: originally

```
int set_primes( int *list , int capacity )
```

// updated

```
int set_primes( int **list , int capacity )
```

// in main function

```
int *list = /* initial allocation of array */
```

// original call to set_primes

```
int prime_count = set_primes( list , capacity );
```

// updated

```
int prime_count = set_primes( &list , capacity );
```

Exercise 11 review

Sketch showing how having `set_primes` take a pointer to a pointer solves the problem:

Exercise 11 review

Changes to `set_primes`: essentially, everywhere that `list` was mentioned, we now want `*list` so that we are referring (indirectly) to the `list` pointer variable in `main`.

One issue: array subscript operator has higher precedence than the pointer dereference operator (`*`)

So, instead of changing

```
list[idx++] = n;
```

to

```
*list[idx++] = n;
```

it should be

```
(*list)[idx++] = n;
```

Day 12 recap questions

- ❶ What output is printed by the “Example code” below?
- ❷ Assume that `arr` is an array of 5 `int` elements. Is the code `int *p = arr + 5; legal?`
- ❸ Assume that `arr` is an array of 5 `int` elements. Is the code `int *p = arr + 5; printf("%d\n", *p); legal?`
- ❹ What output is printed by the “Example code 2” below?
- ❺ Suppose we have variables `int ra1[10] = {1, 2, 3};, int * ra2 = ra1; and int fun(int *ra);` declarations. Will `fun(ra1);` compile? Will `fun(ra2);` compile? What if we change the function declaration to `int fun(const int ra[]);?`

1. What output is printed by the "Example code" below?

```
int arr[] = { 94, 69, 35, 72, 9 };
int *p = arr;
int *q = p + 3;
int *r = q - 1;
printf("%d %d %d\n", *p, *q, *r);
ptrdiff_t x = q - p;
ptrdiff_t y = r - p;
ptrdiff_t z = q - r;
printf("%d %d %d\n", (int)x, (int)y, (int)z);
ptrdiff_t m = p - q;
printf("%d\n", (int)m);
int c = (p < q);
int d = (q < p);
printf("%d %d\n", c, d);
```

if $p + i = q$, then $q - p = i$

p

q

r

94 72 35

3 2 1

-3

x

y

z

m

c

d

$p + i \Rightarrow$ pointer to element i positions
from the element p points

2. Assume that `arr` is an array of 5 `int` elements. Is the code `int *p = arr + 5;` legal?

Yes. It uses pointer arithmetic to compute a pointer 5 elements past the first element of `arr`.

Note that it would not be legal to *dereference* this pointer.

Why such a pointer might be useful: as an upper bound for a loop using a pointer to iterate through the elements of `arr`. E.g.:

```
int *p = arr + 5;
int sum = 0;
for (int *q = arr; q < p; q++) {
    sum += *q;
}
```

3. Assume that `arr` is an array of 5 `int` elements. Is the code `int *p = arr + 5; printf("%d\n", *p);` legal?

No. `p` doesn't point to a valid array element, so dereferencing it is undefined behavior.

4. What output is printed by the “Example code 2” below?

```
#include <stdio.h>
int *a
int sum(int a[], int n) {
    int x = 0;
    for (int i = 0; i < n; i++) {
        x += a[i];
    }
    return x;
}

int main(void) {
    int data[] = { 23, 59, 82, 42, 67, 89, 76, 44, 85, 81 };
    int result = sum(data + 3, 4);
    printf("result=%d\n", result);
    return 0;
}
```

5. Suppose we have variables `int ra1[10] = {1, 2, 3};`, `int * ra2 = ra1;` and `int fun(int *ra);` declarations. Will `fun(ra1);` compile? Will `fun(ra2);` compile? What if we change the function declaration to `int fun(const int ra[]);`?

- ✓ Yes, the name of an array of `int` elements will “decay” into a pointer to the first element of the array if used without the subscript operator.
- ✓ Yes, `ra2` is a pointer to `int`, which is the type of argument expected by `fun`.
- ✓ Yes, a pointer to `int` can be passed to a function expecting pointer to `const int`. (Note that it's *not* allowed to pass a pointer to `const int` to a function expecting a pointer to (non-`const`) `int`.)

Exercise 12

- Using pointer arithmetic to treat regions of arrays as “sub-arrays”
- Using pointer difference to translate a pointer to an element into the element’s index (by subtracting the “base pointer”, i.e., the pointer to the first element)
- Talk to us if you have questions!
