

601.220 Intermediate Programming

Spring 2023, Day 13 (February 20)

Today's agenda

- Exercise 12 review
- Lifetime/scope, struct types, random number generation
- Exercise 13

Reminders/Announcements

- HW3 due Friday (Feb 24th)
 - This is a challenging assignment, don't wait until the last minute
 - Midterm project team registration: soon

Exercise 12 review

Declaration of search function:

How it is called:

```
pos = search(arr1, arr1 + 10, 318);
```

Declaration:

```
int *search(int *start, int *end, int searchval);
```

inclusive

exclusive

Exercise 12 review

Useful property when lower bound of search range is inclusive, and upper bound is exclusive. end - start is the number of elements in the range. So:

```
int *search(int *start, int *end, int searchval) {  
    int num_elts = (int) (end - start);  
    if (num_elts < 1) {  
        return NULL; // no elements in range  
    } else {  
        // general case: check middle element, if it's equal to  
        // searchval, success, otherwise continue recursively on  
        // left or right side of range  
    }  
}
```

Exercise 12 review

```
// search, general case
int *mid = start + (num_elts/2);
if (*mid == searchval) {
    return mid; // success, found the search value
} else if (*mid < searchval) {
    // continue recursively in right side of range
} else {
    // continue recursively in left side of range
}
```

Exercise 12 review

```
// in the test code, finding the index of the matching element  
pos = search(arr1, arr1 + 10, 318);  
assert(pos != NULL);  
assert(*pos == 318);  
// TODO: compute the index of the matching element  
index = pos - arr1; // <-- add this  
assert(2 == index);
```

Exercise 12 review

General observation about 2-D arrays: if p is a pointer to an element, and N is the number of columns in one row, then

$p + N$

yields a pointer to an element that is in the same column and next row from the element p points to. Picture:

Exercise 12 review

makeCol:

```
// TODO: declare the unit variable (array of 9 integers, to be returned)  
int *unit = malloc(9 * sizeof(int));
```

Exercise 12 review

makeCube:

```
// TODO: declare the unit variable (array of 9 integers, to be returned  
int *unit = malloc(9 * sizeof(int));
```

Exercise 12 review

checkRows:

```
// TODO: call check on current row and add to variable good  
good += check(&table[r][0]);
```

Observation: elements in a single row are contiguous in memory (each row of a 2-D array can be treated as a 1-D array).

Exercise 12 review

checkCols:

```
for (int c = 0; c < SIZE; c++) {  
    // TODO: call makeCol on current column and assign result to column  
    column = makeCol(&table[0][c]);    // <-- get one column of values  
    good += check(column);  
    free(column);                      // <-- free dynamic array  
}
```

$c=2$

$N=9$

Exercise 12 review

checkCubes:

```
// TODO: call makeCube on current cube and assign result to variable cube  
cube = makeCube(&table[r][c]);    // <-- get 3x3 "cube" of values  
good += check(cube);    - -  
free(cube);                // <-- free dynamic array
```

Exercise 12 review

`main` (in `sudoku.c`): code does not call `fclose` to close input file: should modify `main` function so that `infile` is guaranteed to be closed (using `fclose`) if it is opened successfully.

Makefile: `CFLAGS` should include the `-g` option (to enable debug symbols).

Running `valgrind`:

```
valgrind ./main --leak-check=full --show-leak-kinds=all <name of input file>
```

Day 13 recap questions

- ① What is *struct* in C?
- ② How are the fields of a struct passed into a function - by value or by reference?
- ③ What is the size of a *struct*? What is structure padding in C?
- ④ What is the difference between lifetime and scope of a variable?
- ⑤ What is variable shadowing (i.e. hiding)?
- ⑥ What is the output of the below program?

1. What is *struct* in C?

struct introduces a *used-defined data type*.

Very much like a class in Java or Python, but with only the ability to include member variables, not member functions.

An instance of a struct is a “bundle” of variables that are packaged as a single entity.

Example:

```
struct Point {  
    int x, y;  
};
```

```
// ... elsewhere in the program ...  
struct Point p = { .x = 2, .y = 3 };
```

2. How are the fields of a struct passed into a function - by value or by reference?

Instances of a struct type are passed by value. E.g.

```
struct Point { int x, y; };
```

```
void f(struct Point p, int dx) {  
    p.x += dx;  
}
```

```
int main(void) {  
    struct Point q = { .x = 4, .y = 5 };  
    f(q, -2);  
    printf("%d,%d\n", q.x, q.y); // prints "4,5"  
    return 0;  
}
```

3. What is the size of a *struct*? What is structure padding in C?

`sizeof(struct Foo)` is the sum of the sizes of the fields of struct Foo, plus the total size of any padding inserted by the compiler to ensure that fields are correctly aligned.

alignment: the memory address of a variable (including a field variable in an instance of a struct type) must be a multiple of the size of the field.

E.g., a 4-byte `int` variable (or struct field) must have its storage allocated starting at a machine address that is a multiple of 4.

The compiler will insert padding automatically: you don't need to do anything special. `sizeof(struct Foo)` will always take the padding into account. Just trust that the compiler will figure out the right struct layout to use.

struct padding example

```
struct Foo {  
    char a;  
    int b;  
    long c;  
};  
  
// ...  
  
struct Foo f;  
printf("%lu\n", sizeof(f));
```

4. What is the difference between lifetime and scope of a variable?

dynamic **Lifetime:** the interval from (1) the point in time when a variable is created, to (2) the point in time when a variable is destroyed. Examples:

- the lifetime of a local variable is the duration of the function call
- the lifetime of a global variable is the duration of the entire program

Scope: the region of the program code in which a variable may be accessed. Examples:

"block" → { ... }

- static*
- the scope of a local variable is from its declaration to the closing "}" of the block in which it's defined
 - the scope of a global variable is the entire program (assuming that there is a declaration or definition of the variable in the current block, or in the enclosing block)

5. What is variable shadowing (i.e. hiding)?

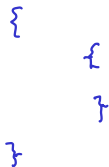

Diagram illustrating variable shadowing using nested curly braces. An outer scope is represented by a large blue curly brace on the left. Inside it, a smaller blue curly brace represents a nested scope. This visualizes how a variable declared in the inner scope shadows the variable with the same name in the outer scope.

Shadowing: a variable declaration in a nested scope has the same name as a variable in an “outer” scope.

Shadowing example

The diagram illustrates variable shadowing in C. It shows three scopes: global, function `foo`, and function `main`.
1. Global scope: `int x;`
2. Function `foo`:
 - Parameter `int x` is shadowed by the function parameter.
 - Local variable `int x = 5;` is shadowed by the parameter.
 - `printf("%d\n", x);` prints 5, using the parameter `x`.
 - `printf("%d\n", x);` prints 4, using the parameter `x`.
3. Function `main`:
 - `int x = 3;` is the only `x` in this scope.
 - `foo(4);` passes 4 to the parameter `x` of `foo`.
 - `printf("%d\n", x);` prints 3, using the `x` in `main`.
Pink arrows and circles highlight the shadowing relationships: from the global `x` to the `foo` parameter, from the `foo` parameter to its local `x`, and from the `main` `x` to its `printf` statement.

```
int x;  
  
void foo(int x) {  
    {  
        int x = 5;  
        printf("%d\n", x); // prints "5"  
    }  
    printf("%d\n", x); // prints "4"  
}  
  
int main(void) {  
    x = 3;  
    foo(4);  
    printf("%d\n", x); // prints "3"  
    return 0;  
}
```

6. What is the output of the below program?

```
#include <stdio.h>
```

```
int foo;
```

```
void bar() {
```

```
    int foo = 3;
```

```
{
```

```
    extern int foo;
```

```
    printf("%d; ", foo);
```

```
    foo = 2;
```

```
}
```

```
    printf("%d; ", foo);
```

```
}
```

```
void baz() { printf("%d; ", foo); }
```

```
int main() {
```

```
{
```

```
    int foo = 5;
```

```
    bar();
```

```
    printf("%d; ", foo);
```

```
}
```

```
baz();
```

```
return 0;
```

```
}
```

same

. VS. ->

To access a member variable of a struct instance directly, use the “.” operator. To access a member variable of a struct instance indirectly via a pointer, use the -> operator.

Note that $p \rightarrow x$ means exactly the same thing as $(*p).x$. It's just a more convenient syntax.

struct Foo x;

... x.f

if x is an instance
of a struct type

struct Foo *x;

... x->f

if x is a pointer to
an instance of a struct type

Example of . vs. ->

```
struct Player { int x; int y; int health; };
```

```
struct Player player;
```

```
player.x = 42;
```

```
player.y = 17;
```

```
struct Player *p = &player;
```

```
p->health = 100;
```

Exercise 13

- Working with struct types, including pointers to instances of struct types
- Talk to us if you have questions!
